

Mobile App Developer

Step 1: Learn Programming Basics

CareerCompass — Detailed Learning Notes

What this step is about

Build the programming foundation needed for mobile development before learning a framework.

Core Concepts

- Choose a primary language: Kotlin/Java for Android, Swift for iOS, or Dart/JavaScript for a cross-platform stack.
- Master variables, types, operators, conditions, loops, functions, collections, classes, exceptions and debugging.
- Understand event-driven programs, asynchronous work, state, dependencies and basic software architecture.
- Practice Git and documentation from the beginning; do not rely only on copy-pasting tutorial code.

Skills You Should Be Able To Demonstrate

- Write small programs without a tutorial.
- Use a debugger to find a runtime error.
- Explain classes, objects, collections and exceptions.
- Create a small reusable module/function instead of one large file.

Hands-on Project / Practice

- Build a small Notes or Expense app with add/edit/delete/search using local in-memory data first.
- Refactor it into separate model, UI and logic layers.
